A. Option C
B. Option B
C. Option A
D. Option D
Answer: D

Conditional forwarders are DNS servers that only forward queries for specific domain names. Instead of forwarding all queries it cannot resolve locally to a forwarder, a conditional forwarder is configured to forward a query to specific forwarders based on the domain name contained in the query. Forwarding according to domain names improves conventional forwarding by adding a name-based condition to the forwarding process.

The conditional forwarder setting for a DNS server consists of the following:

The domain names for which the DNS server will forward queries. One or more DNS server IP addresses for each domain name specified.

When a DNS client or server performs a query operation against a DNS server, the DNS server looks to see if the query can be resolved using its own zone data or the data stored in its cache. If the DNS server is configured to forward for the domain name designated in the query, then the query is forwarded to the IP address of a forwarder associated with the domain name. For example, in the following figure, each of the queries for the domain names is forwarded to a DNS server associated with the domain name.

A switch can be partitioned to create a VLAN dedicated to HMC to managed server communication. If HMCs are configured as DHCP servers, there must be only one HMC on each VLAN! If dual HMCs are attached for redundancy, it is unwise to connect the HMCs to two VLANs in the same switch, because if the switch fails both HMCs lose connectivty, thereby defeating the HMC redundancy

NEW QUESTION: 3
What size is an MD5 message digest (hash)?
A. 160 bits
B. 256 bits
C. 128 bits
D. 128 bytes

Answer: C
Explanation:
"MD4 MD4 is a one-way hash function designed by Ron Rivest. It produces 128-bit hash, or message digest, values. It is used for high-speed computation in software implementations and is optimized for microprocessors.
MD5 MD5 is the newer version of MD4. It still produces a 128-bit hash, but the algorithm is more complex, which makes it harder to break. MD5 added a fourth round of operations to be performed during the hashing functions and makes several of it mathematical operations carry out more steps or more complexity to provide a higher level of security.
MD2 MD2 is also a 128-bit one-way hash designed by Ron Rivest. It is not necessarily any weaker than the previously mentioned hash functions, but is much slower.
SHA SHA was designed by NIST and NSA to be used with DSS. The SHA was designed to be used with digital signatures and was developed when a more secure hashing algorithm was required for federal application. SHA produces a 160-bit hash value, or message digest. This is then inputted into the DSA, which computes the signature for a message. The message digest is signed instead of the whole message because it is a much quicker process. The sender computes a 160-bit hash value, encrypts it with his private key (signs it), appends it to the message, and sends it. The receiver decrypts the value with the sender's public key, runs the same hashing function, and compares the two values. If the values are the same, the receiver can be sure that the message has not been tampered with in transit. SHA is similar to MD4. It has some extra mathematical functions and produces a 160-bit hash instead of 128-bit, which makes it more resistant to brute force attacks, including birthday attacks.
HAVAL HAVAL is a variable-length one-way hash function and is the modification of MD5. It processes message blocks twice the size of those used in MD5; thus it processes blocks of 1,024 bits.
